ABSTRACT

Pressure vessels are being widely employed worldwide as means to carry, store or receive fluids. The pressure differential is dangerous and many fatal accidents have occurred in the history of their development and operation. Torispherical Heads have a dish with a fixed crown radius (CR), the size of which depends on the type of torispherical head. The transition between the cylinder and the dish is called the knuckle. The knuckle has a toroidal shape. Torispherical heads require less forming than semi-ellipsoidal heads. The aim of the research is to carry out Buckling analysis in a torispherical head pressure vessel due to applied internal pressure. The analyses characteristics are investigated by Finite Element Method software. For Buckling, a pressure vessel will be designed and then model educing Solid Edge software. Buckling analysis is carried out to determine the buckling strength. The research is aimed to analyze torispherical head pressure vessel for different internal pressures.

Keywords: Pressure vessel, Torispherical Heads, Buckling analysis, Stress Intensity Factor.

I. INTRODUCTION

The predicted lifespan of parts and components is a key question regarding the safety of certain components, such as pressure vessels, airplanes, cars, or with regard to the reliability of micro-electronic components or implants in the human body.

Pressure vessels to store substances under pressure higher than atmospheric conditions and are found all over the place. They are used in homes and hospitals for hot water storage, in many different factories and plants, and in mining and oil refineries. Pressure vessels store large amounts of energy. The higher the operating pressure and the bigger the vessel, the more the energy released in the event of an accident and consequently the higher the extent of damage or disaster or the danger it poses, hence there should be no complacency about the risks. Unfortunately, pressure vessels accidents happen much more than they should.

The objective of the Research is to identify the Critical Buckling Pressure for Torispherical Head Pressure Vessel subjected to various Internal Pressures.

II. METHODOLOGY

To achieve the objectives listed above the following steps are considered:

• Designing of a torispherical head pressure vessel
• Modeling the pressure vessel as per design data
• Buckling analysis using ANSYS software
• Finding the Buckling Pressure.

III. DESIGN DETAILS

3.1 Material Selection

By literature survey we have selected the material as SA-240 304, which is widely used for pressure vessels. Type 304 stainless steel is a variation of 18% chromium - 8% nickel austenitic alloy, the most familiar and most frequently used alloy in the stainless steel family. These alloys may be considered for a wide variety of applications: resistance to corrosion, prevention of product contamination, resistance to oxidation, ease of fabrication, excellent formability, beauty of appearance, ease of cleaning high strength with low weight, good strength and toughness at cryogenic temperatures, ready availability of a wide range of product forms. Table 1 shows the chemical composition of material SA-240304.

Mechanical & Physical properties
• Density, $\rho = 8.03 \text{g/cm}^3$
• Modulus of rigidity, $E = 200 \text{GPa}$
• Yield strength, $\sigma_y = 215 \text{MPa}$
• Tensile strength, $\sigma_t = 505 \text{MPa}$
• Hardness, $= 201 \text{BHN}$

3.1.1 Thickness Calculations

Assumptions

Internal Pressure, $P_i = 5 \text{N/mm}^2$
Internal Diameter, $D_i = 1000 \text{mm}$

Poisson’s ratio, $\mu = 0.29$

$\sigma_h = \frac{P_i r_i}{t} = \frac{5 \times 500}{t} = \frac{2500}{t} \text{N/mm}^2$  (3.1)

$\sigma_a = \frac{P_i r_i}{2t} = \frac{5 \times 500}{2t} = \frac{1250}{t} \text{N/mm}^2$  (3.2)

Where, $\sigma_h =$ Hoop or Tangential stress
$\sigma_a =$ Axial stress

According to Von-Mises criterion,

$\sigma_y = \sqrt{\sigma_h^2 + \sigma_a^2 - (\sigma_h \cdot \sigma_a)}$  (3.3)

$\Rightarrow 215^2 = (\frac{2500}{t})^2 + (\frac{1250}{t})^2 - [(\frac{2500}{t}) \times (\frac{1250}{t})]

\text{Thickness calculation for Torispherical head}

According to UG 31 of ASME sec VIII Div 1, minimum thickness required is given by

$t = \frac{(P_i D_i) + C}{(2 \sigma_y E) - (0.2 P_i)}$  (3.4)

Where,

$C =$ Corrosion allowance $= 3 \text{mm}$
$E =$ Efficiency of the joint $= 1.0$

$\Rightarrow t = \frac{(5 \times 1000) + 3}{(2 \times 215 \times 1) - (0.2 \times 5)}$

$T_{th s}, t = 11.66 \text{ mm} \approx 12 \text{ mm}$

Therefore, taking the higher value for thickness as $12 \text{ mm}$
Dimensions of cylinder
- Inner radius, \( r_i = 500 \text{mm} \)
- Outer radius, \( r_o = r_i + t = 512 \text{mm} \)
- Length of the cylinder, \( L_c = 2000 \text{mm} \)

Dimensions of Torispherical head
- Crown radius, \( L = d_o = 1024 \text{mm} \)
- Knuckle radius, \( r = 0.1 \ d_o = 102.4 \text{mm} \)
- Straight Flange, \( SF = 3.5 \ t = 42 \text{mm} \)
- Dished height, \( DH = (0.1935 \ d_o) - (0.455 \ t) = 192.684 \text{mm} \)
- Total head height, \( T_{Hi} = SF + DH = 234.684 \text{mm} \)

3.2 Finite element Model Development

3.2.1 Shell 93 (8 node) element description
- SHELL 93 is particularly well suited to model curved shells.
- The element has six degrees of freedom at each node: translations in the nodal x, y, and z directions and rotations about the nodal x, y, and z-axes.
- The deformation shapes are quadratic in both in-planedirections.
- The element has plasticity, stress stiffening, large deflection, and large strain capabilities.
- The geometry, node locations, and the coordinate system for this element are shown in Figure 1.

![Shell 93(8 Node) Geometry](image)

- The element is defined by eight nodes, four thicknesses, and the orthotropic material properties.
- A triangular-shaped element may be formed by defining the same node number for nodes K, L, and O.

3.2.2 Model for buckling analysis
Eigenbuckling analysis of 3D torispherical head subjected to internal pressure of 1 MPa to 3 MPa is performed to determine the critical buckling load and to predict the buckling mode shape under internal pressure. The eigenvalue approach takes the results obtained from the static analysis. Hence we first solve for the static analysis and then run the eigen value buckling. In this case the static analysis follows the same procedure as explained in previous section. The Geometry of the 3D torispherical head is shown in Figure 2. In this study, 8 node SHELL 93 is used as element. The Dimensions of the torispherical head is shown in Table 2.

4.1 Buckling Analysis

The Eigen value buckling analysis of 3D torispherical head subjected to internal pressures of 1 Mpa, 2 Mpa and 3 Mpa is performed. The parametric study is performed to determine the critical buckling load of the vessel. The effect of parameter such as internal pressure variation on the torispherical head is shown in the below. Buckling shape of the vessel having thickness 12 mm subjected to an internal pressure of 1 MPa, 2Mpa and 3MPa is shown in Figures, Fig.3 to Fig.8. By the method of Eigen value buckling analysis, the critical buckling pressure at which the vessel undergoes buckling is found to be,

- 234.795 MPa for 1 MPa internal pressure
- 117.400 MPa for 2 MPa internal pressure
- 078.266 MPa for 3 Mpa internal pressure

The vessel buckling is seen in knuckle region because of geometric discontinuity. The values of buckling stress for each mode is shown in the below table 3.

</table>

The vessel buckling is seen in knuckle region because of geometric discontinuity. The values of buckling stress for each mode is shown in the below table 3.
Buckling Analysis of Torispherical Head Pressure Vessel Using Finite Element Analysis

Fig. 9: Variation of critical buckling pressure for 1 MPa internal pressure

Fig. 10: Variation of critical buckling pressure for 2 MPa internal pressure

Fig. 11: Variation of critical buckling pressure for 3 MPa internal pressure

Fig 9, 10 & 11 shows the variation of Buckling Pressure for various modes. From the figure it is evident that the Buckling Pressure is decreasing with increase in internal Pressure.

V. CONCLUSION AND SUGGESTIONS FOR FUTURE WORK

5.1 Conclusion

From the finite element analysis performed on a torispherical head pressure vessel subjected to different internal pressures, the following conclusions were made:

- Eigen value buckling analysis was carried out to determine the critical buckling pressure at which the vessel undergoes buckling effects. It was found that time taken to buckle is more for least pressure and goes on increasing as the pressure increases. Based on the study performed to determine the critical buckling pressure of the vessel, buckling pressure is influenced by the thickness of the vessel. Higher the thicknesses of the vessel better the buckling resistance.
